Point Detection

Line Detection

Edge Detection

Laplacian of  
Gaussian (LoG)

- 1 Filter the input image  $f(x, y)$  with Laplacian  $H_{lap}$ , i.e., compute  $g(x, y) = f(x, y) * H_{lap}(i, j)$
- 2 Detect isolated points  $(x, y)$  if they satisfy:  
 $|g(x, y)| \geq T$ . Where,  $T$  is a threshold value.

Laplacian kernel  $H_{lap}$ :

$$H_{lap} = \begin{bmatrix} -1 & -1 & -1 \\ -1 & 8 & -1 \\ -1 & -1 & -1 \end{bmatrix}$$

# Line Detection

- 1 Filter the input image  $f(x, y)$  with all following masks for detecting horizontal, vertical,  $\pm 45^\circ$ -oriented lines. This process results  $g_i(x, y), i = 1..4$ . You can design new masks for other lines with new orientation.
- 2 Chose a orientation  $i$  for point  $(x, y)$  by selecting the largest  $g_i(x, y), i = 1..4$ .
- 3 Do thresholding with a certain  $T$  (input) to obtain lines.

Some kernels:

$\begin{bmatrix} -1 & -1 & -1 \\ 2 & 2 & 2 \\ -1 & -1 & -1 \end{bmatrix}$	$\begin{bmatrix} -1 & 2 & -1 \\ -1 & 2 & -1 \\ -1 & 2 & -1 \end{bmatrix}$
Horizontal	Vertical
$\begin{bmatrix} -1 & -1 & 2 \\ -1 & 2 & -1 \\ 2 & -1 & -1 \end{bmatrix}$	$\begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix}$
$+45^\circ$	$-45^\circ$

## Definition

Edge is a set of connected pixels that lie on the boundary between two regions.

## Properties

- 1 There is "meaningful" transitions in gray-levels at edge.
- 2 So, first-order and second-order derivatives can be used to detect the transition.

# Edge Detection

Examples of Derivatives: image, a line profile, first and second-order derivatives.

Model of edges:

- ① Left: **Clear edge or Ideal edge**, ideally represented as a step
- ② Middle: **Blurred edge**, ideally represented as a ramp
- ③ Right: **A blurred bright edge**, ideally represented as a roof.

Point Detection

Line Detection

Edge Detection

Laplacian of  
Gaussian (LoG)

## Edge with first-order derivatives

Edge consists of points where the module of the gradient vector is greater than a threshold.

- The gradient vector is **perpendicular** with the local edge passing that point

# Edge Detection

## Edge with second-order derivatives

Edge consists of **zero-crossing points** in image filtered with second-order derivatives.

- Second-order derivatives create one **positive** response and another **negative** one for ramp edges.

# Edge Detection with noise

- Rows: Row 1: no noise; Row 2: with Gaussian noise ( $\mu = 0, \sigma = 0$ )
- Cols: Col 1: a line profile; Col 2: **First-order derivative**; Col 3: **Second-order derivative**

# Edge Detection with noise

- Rows: Row 1: with Gaussian noise ( $\mu = 0, \sigma = 0.1$ );  
Row 2: with Gaussian noise ( $\mu = 0, \sigma = 1.0$ )
- Cols: Col 1: a line profile; Col 2: **First-order derivative**;  
Col 3: **Second-order derivative**

## Properties

- Second-order derivative is more **sensitive to noise** compared with first-order derivative.
- However,
  - First-order derivatives provide **thick edges**
  - Second-order derivatives provide **thin edges** (via, zero-crossing)

## Question

Laplacian can provide the discontinuity in gray-levels. **Why is it not used in edge detection?**

## Reasons

- ① As a second-order derivative, it is unacceptably sensitive to noise
- ② The magnitude of Laplacian provides double edges (one for positive and another one for negative response)
- ③ Laplacian can not provide edge direction

Therefore, Laplacian is directly suitable for sharpening images only.

# Edge Detection and Laplacian

- Laplacian can provide thin edges via zeros-crossing detection. However, it is sensitive to noise.
- What will be happened if we remove noise before taking Laplacian and then finding zeros-crossing?

## Laplacian in edge detection

- ① Perform noise removal with a Gaussian low-pass filter. The input image will be blurred.
- ② Apply Laplacian to the resulting image.
- ③ Detect zero-crossing points to obtain edge points.

## Laplacian of Gaussian (LoG)

**Step 1 and 2 in the above algorithm is equivalent to filtering image with a LoG mask**

# Laplacian of Gaussian (LoG)

Point Detection

Line Detection

Edge Detection

Laplacian of  
Gaussian (LoG)

## A Gaussian function $G(x, y)$

$$G(x, y) = e^{-\frac{x^2+y^2}{2\sigma^2}}$$

- $\sigma$  : standard deviation. **This parameter decides the degree of blurring in output image, if the input image is convoluted with this function**

# Laplacian of Gaussian (LoG)

Point Detection

Line Detection

Edge Detection

Laplacian of  
Gaussian (LoG)

## Laplacian of Gaussian (LoG)

$$\nabla^2 G(r) = \left[ \frac{x^2 + y^2 - 2\sigma^2}{\sigma^4} \right] e^{-\frac{r^2}{2\sigma^2}}$$

- LoG  $\equiv$  Laplacian of function  $G(x, y)$
- LoG  $\equiv \frac{\partial^2 G(x, y)}{\partial x^2} + \frac{\partial^2 G(x, y)}{\partial y^2}$

# Laplacian of Gaussian (LoG)

0	0	-1	0	0
0	-1	-2	-1	0

Point Detection

Line Detection

Edge Detection

Laplacian of  
Gaussian (LoG)

## Properties

- ① Other name: Mexican hat, because of its shape
- ② Zero-crossing point in LoG:  $x^2 + y^2 = 2\sigma^2$
- ③ Radius from the origin to zero-crossing point:  $r = \sqrt{2}\sigma$
- ④ Kernel of LoG given above: just an example. It can be approximated by any size and any coefficients.
- ⑤ **Sum of all coefficients of the kernel must be 0**

## Generation of LoG's kernel

How can you generate LoG's kernel?

# Laplacian of Gaussian (LoG)

Point Detection

Line Detection

Edge Detection

Laplacian of  
Gaussian (LoG)

## Properties: Linearity

$$\begin{aligned}g(x, y) &= [\nabla^2 G(x, y)] * f(x, y) \\ &= \nabla^2 [G(x, y) * f(x, y)]\end{aligned}$$

## Marr-Hildreth Algorithm

- 1 **Filter** the input image  $f(x, y)$  with Gaussian low-pass filter by kernel size  $n \times n$  to obtain the output  $g(x, y)$ .
- 2 **Compute** Laplacian of  $g(x, y)$  to obtain  $g_L(x, y)$
- 3 **Find** zero-crossing points in  $g_L(x, y)$

## LoG

Step 1 and 2 can be implemented as applying LoG on the input image.

## Power of Marr-Hildreth Algorithm

Marr-Hildreth Algorithm can remedy the following problems in edge detection:

- ① Intensity changes are not independent of image scale  $\Rightarrow$  use different kernel' size.
- ② Edges are sensitive to noise, especially true for second-order derivative  $\Rightarrow$  use Gaussian low-pass filter

## Questions

- ① How can you obtain the kernel's size?
- ② How can you detect zero-crossing points?

## How can you obtain the kernel's size?

- Volume of a Gaussian function inside of circle  $radius = 3\sigma$  is 99.7%
- $\Rightarrow$  Kernel size  $n \times n$ , where  $n$  an odd number  $\geq 6\sigma$

## How can you detect zero-crossing points?

- 1 Perform thresholding of the magnitude of LoG image, i.e.  $|g_l(x, y)|$ , with a value  $T$ .

$$g_l(x, y) = \begin{cases} -1 & \text{if } (g_l(x, y) < 0) \text{ and } |g_l(x, y)| > T \\ 1 & \text{if } (g_l(x, y) > 0) \text{ and } |g_l(x, y)| > T \\ 0 & \text{otherwise} \end{cases}$$

- 2 Apply a mask  $3 \times 3$  at each pixel on  $g_l(x, y)$ .

NW	N	NE
W	C	E
SW	S	SE

- 3 Detect the difference on the sign at opposing corners, i.e., (W, E), (N, S), (NW, SE), and (SW, NE).
- 4 If any pair of corners results a difference on the sign, then  $g_l(x, y)$  is an edge point.

**Figure:** Marr-Hildreth Algorithm: (a): Result of Step 1 and 2, (b): Zero-crossing of (a), Threshold = 4% of maximum value in (a)

- Step 1 and 2:  $\sigma = 4, n = 25$  (kernel's size:  $25 \times 25$ )
- Larger threshold  $\Rightarrow$  provide strong edge only

## Canny Edge Detection Algorithm

- ① Smooth the input image with Gaussian low-pass filter
- ② Compute the gradient magnitude angle images
- ③ Apply nonmaxima suppression to the gradient magnitude image.
- ④ Use double thresholding and connectivity analysis to detect and link edges

## Step 1: Smooth the input image with Gaussian low-pass filter

- ① Smooth the input image with Gaussian low-pass filter
- ② Compute the gradient magnitude angle images
- ③ Apply nonmaxima suppression to the gradient magnitude image.
- ④ Use double thresholding to obtain strong and weak edge masks
- ⑤ Analyze the connectivity to detect and link edges

## Step 1: Smooth the input image with Gaussian low-pass filter

$$G(x, y) = e^{-\frac{x^2+y^2}{2\sigma^2}}$$

$$f_s(x, y) = f(x, y) * G(x, y)$$

- $f_s(x, y)$  : a smoothed version of  $f(x, y)$
- $\sigma$  : decides the degree of smoothing
- $f_s(x, y)$  : Gaussian noise has been removed

## Step 2: Compute the gradient magnitude angle images

- Compute  $g_x(x, y)$  and  $g_y(x, y)$

$$g_x(x, y) = f_s(x, y) * H_x(x, y)$$

$$g_y(x, y) = f_s(x, y) * H_y(x, y)$$

- $H_x(x, y)$ ,  $H_y(x, y)$ : any first-order derivative kernels, e.g., "standard" approximations kernels, Sobel, Roberts, Prewitts, etc.
- Compute gradient magnitude and angle images

$$M(x, y) = \begin{bmatrix} g_x(x, y) \\ g_y(x, y) \end{bmatrix}$$

$$\alpha(x, y) = \tan^{-1} \left[ \frac{g_y(x, y)}{g_x(x, y)} \right]$$

## Step 3: Apply nonmaxima suppression to the gradient magnitude image.

### The underlying idea of **nonmaxima suppression**

if a point is not a local maxima, then suppress (remove, stop, etc) it.

- Edges will pass points that are **local maxima** in gradient magnitude image, ie.,  $M(x, y)$ .
- $\Rightarrow$  Remove (suppress) points that are not local maxima.
- $\equiv$  **nonmaxima suppression**

# Canny Edge Detection

Edge Detection

LE Thanh Sach

Point Detection

Line Detection

Edge Detection

Laplacian of  
Gaussian (LoG)

Step 3: Apply nonmaxima suppression to the gradient magnitude image.

## Questions

What does **local** mean?

- **local**  $\equiv$  local points involving in edge.
- for a point  $(x, y)$  in  $M(x, y)$ , **which neighbor points are edge local points?**
- $\Rightarrow$  need gradient angle

Gradient vector at a point is **perpendicular** to local edge at that point.

## Step 3: Apply nonmaxima suppression to the gradient magnitude image.

- 1 Discrete gradient angle values into small ranges.
- 2 Find direction  $d_k$  that is closest to  $\alpha(x, y)$
- 3 Find local neighbors on edge using  $d_k$ , referred to as  $N_1$  and  $N_2$
- 4 Compute nonmaxima suppressed image  $g_N(x, y)$

$$g_N(x, y) = \begin{cases} 0 & \text{if } [M(x, y) < N_1] \& [M(x, y) < N_2] \\ M(x, y) & \text{otherwise} \end{cases}$$

# Canny Edge Detection

**Step 3: Apply nonmaxima suppression to the gradient magnitude image.**

**Figure:** Demonstration for 4 directions: horizontal, vertical,  $\pm 45^\circ$

## Step 4: Use double thresholding to obtain strong and weak edge masks

- 1 Do thresholding with high and low threshold value  $T_H$  and  $T_L$  respectively.

$$g_{NH}(x, y) = g_N(x, y) \geq T_H$$

$$g_{NL}(x, y) = g_N(x, y) \geq T_L$$

- 2 Eliminate points in  $g_{NL}(x, y)$  that has been indicated in  $g_{NH}(x, y)$

$$g_{NL}(x, y) = g_{NL}(x, y) - g_{NH}(x, y)$$

- $g_{NH}(x, y)$ : strong edge
- $g_{NL}(x, y)$ : weak edge

## Step 5: Analyze connectivity and to detect and link edges

- 1 Create an **edge map** that marks all non-zeros in  $g_{NH}(x, y)$  as valid edge points.
- 2 For each pixel  $p$  that is non-zeros in  $g_{NH}(x, y)$ , do
  - Find all non-zeros pixels in  $g_{NL}(x, y)$  that are connected to  $p$  via 4- or 8-connectivity, mark corresponding points in **edge map** as valid pixels.

- **edge map** may contain edges thicker than 1 pixel.
- Apply edge-thinning algorithm to create thinner edge map, if needed.
